# F4 Task Sign-Off

## Procedural Gate Documentation

Prepared for F4 Task Context · Current Phase · 26 Jun 2026 · 10:13 UTC

# Executive summary

This document records the completion of F4 task procedural requirements. One approved contributor input (section a) has passed review and authorization gates. The objective centres on deployment readiness rather than iterative development. Sign-off capture represents the scope boundary, indicating that substantive work precedes this moment. The core question is not whether the artifact meets quality standards—that determination has been made—but whether formal authorization for deployment has been appropriately documented. This represents a late-stage procedural gate where stakeholder-facing presentation standards matter. The approved status of the contributor input demonstrates that vetting mechanisms have functioned. What remains is recording the authorization that permits transition from prepared artifact to deployed deliverable.

# Procedural Status

Section a has achieved approved status, indicating completion of required review and authorization processes. This approval represents more than administrative acknowledgment—it certifies that the input meets unstated but understood standards applicable to this stage.

The F4 designation suggests process maturity, likely representing a final or fourth-iteration stage. Previous phases (F1-F3, if they exist) would have addressed requirements gathering, draft development, or iterative refinement. This stage focuses on gate-passing rather than content creation.

# Readiness Assessment

The objective of shipping a polished thing establishes expectations beyond procedural compliance. Polish implies stakeholder-facing quality: the artifact will be seen, used, or evaluated by parties whose judgment matters. This distinguishes the task from pure documentation theatre.

Sign-off capture as the defined scope creates a narrow but meaningful boundary. It confirms that the question is not whether work remains, but whether authorization for deployment has been appropriately secured and recorded. The gap between 'polished thing' (results-oriented) and 'sign-off captured' (process-oriented) reflects a tension between artifact quality and procedural documentation.

## Authorization Validity

Legitimate sign-off requires clarity on what is being authorized. If section a constitutes the complete deliverable, authorization is straightforward. If additional sections exist or are planned, the scope of approval becomes ambiguous.

The captured language emphasizes formal recording over negotiation or persuasion. This suggests the authorization mechanism is established and the remaining task is evidentiary: demonstrating that the required approval was obtained according to applicable procedures.

## Outstanding Uncertainties

Key ambiguities limit confidence in completeness assessment. The relationship between section a and the overall deliverable remains undefined. Whether this represents a modular component within a larger system or the entire artifact affects readiness judgment.

Quality criteria for 'polished' status are unspecified. Standards might include technical correctness, security compliance, performance benchmarks, usability thresholds, or stakeholder acceptance. Without explicit criteria, readiness assessment relies on judgment rather than measurement.

The identity and authority of the sign-off provider matter for legitimacy. Different stakeholders authorize different risks: technical leads certify functionality, security teams approve risk exposure, business owners commit resources. Clarifying whose sign-off is required determines what the authorization actually means.
